(54) Integrated air control valve using contactless technology

(57) A control valve assembly (10) for the rotary or linear actuation of control valves (16) using contactless technology and the use of direct integration of electronic componentry into a lead frame interconnection assembly (18) includes a contactless motor, a control valve in mechanical communication with the contactless motor (14) through a gear system, and a lead frame interconnection assembly having electronic componentry relevant to the contactless motor and the control valve integrally formed therein. The contactless motor includes a commutator magnet disposed on a rotor shaft thereof. The commutator magnet (46) is in magnetic communication with at least two commutator chips (48) integrally formed with the lead frame interconnection assembly. The control valve includes a throttle element (26) disposed in a throttle bore, an output shaft (20) depending from the throttle element, and at least one position sensing magnet (38) disposed on an end of the output shaft distal from the throttle element. The position sensing magnet is in magnetic communication with at least one position sensor (44) integrally formed with the lead frame interconnection assembly. The throttle element may be a throttle plate rotatably positioned within the throttle bore, or it may be a linearly translatable device.

Fig. 1.

Description**TECHNICAL FIELD**

[0001] This disclosure relates to the actuation of control valves, and, more particularly, to the rotary and linear actuation of control valves using contactless technology integrated with control valve actuation mechanisms.

BACKGROUND OF THE INVENTION

[0002] The use of motors in numerous consumer applications leads to a desire for more reliable, efficient and cost effective manufacture and fabrication of the motors. The utilization of multiple pole motors (e.g., brushless direct current (BLDC) motors) as rotational or linear actuators for use in air flow control valves poses problems that are oftentimes inimical to the efficiency of the motor manufacturing processes. One such problem results from the fabrication of a complex machined stator assembly of the motor. Such a stator assembly requires detailed, expensive, and labor-intensive manufacturing operations. Furthermore, such a machined stator assembly is commonly machine wound and installed into the housing of the motor and is not readily or easily serviced or replaced.

[0003] The multiple pole motors and rotational or linear actuators also typically require that connections be made between the motors, the actuators and a circuit board or a lead frame interconnection assembly. The connections, which are commonly made by hand, typically add additional steps to the assembly processes of the finished products. Furthermore, mechanical interconnections, such as those effectuated through soldering processes, are common in the assembly of motors for use as actuators. Such mechanical interconnections, and particular those in which soldering is used, may pose environmental and health related concerns. In either case, the issues involved are potentially threatening to the efficient and cost effective manufacture of multiple pole motors.

SUMMARY

[0004] A control valve assembly for the rotary or linear actuation of control valves using contactless technology and the use of direct integration of electronic componentry into a circuit board or lead frame interconnection assembly is described herein. The assembly includes a contactless motor, a control valve in mechanical communication with the contactless motor through a gear system, and a lead frame interconnection assembly having electronic componentry relevant to the contactless motor and the control valve integrally formed therein. The contactless motor includes a commutator magnet disposed on a rotor shaft thereof. The commutator magnet is in magnetic communication with at least two

commutator chips integrally formed with the lead frame interconnection assembly. The control valve includes a throttle element disposed in a throttle bore, an output shaft depending from the throttle element, and at least one position sensing magnet disposed on an end of the output shaft distal from the throttle element. The position sensing magnet is in magnetic communication with at least one position sensor integrally formed with the lead frame interconnection assembly. The throttle element 5 may be a throttle plate rotatably positioned within the throttle bore, or it may be a linearly translatable device positioned in the throttle bore.

26 within the throttle bore and define a throttle valve axis about which throttle plate 26 rotates to meter the flow of air through the throttle bore.

[0008] Output shaft 20 is driven by an output gear 30 mounted thereon. Output gear 30 is driven by motor 14 through a configuration of idler gears 32, which are in turn driven by a pinion 36 disposed on rotor shaft 12. Pinion 36 transmits torque from motor 14 through idler gears 32 simultaneously reducing the torque and applying the torque to output gear 30.

[0009] Disposed on an end of output shaft 20 distal from throttle plate 26 are position sensing magnets 38. Position sensing magnets 38 are fixedly mounted circumferentially about an outer surface of output shaft 20 and extend beyond the end of output shaft 20 to define a recess bounded circumferentially by position sensing magnets 38 and by an end surface 40 of output shaft 20 at one end of the recess. The positioning of position sensing magnets 38 is such that magnetic flux lines radiate parallel to the axis of rotation of output shaft 20. The rotation of output shaft 20 effectuates the angular motion of position sensing magnets 38 about the throttle valve axis.

[0010] Positioned on lead frame interconnection assembly 18 proximate the end of output shaft 20 is a position sense flux carrier 42. Position sense flux carrier 42 comprises at least two crescent-shaped members having spaces therebetween arranged to form a cylindrical structure. The cylindrical structure is dimensioned to be accommodated within the recess defined by the configuration of position sensing magnets 38 disposed on the end of output shaft 20. Position sensing magnets 38 effectuate the generation of a magnetic field that varies with the rotation of output shaft 20, while position sense flux carrier 42 provides a flux path for the varying magnetic field.

[0011] A position sensor 44 is positioned on lead frame interconnection assembly 18 in a space between two of the crescent-shaped members that are arranged to form the cylindrical structure of position sense flux carrier 42. Position sensor 44 is a magnetic sensor that is responsive to variations in the magnetic field generated by the angular motion of position sensing magnets 38 about position sense flux carrier 42. The varying magnetic field sensed by position sensor 44 is thereby converted to a voltage value that is used to provide feedback to the operator of assembly 10. Such feedback typically includes data relative to the amount of rotation of throttle plate 26 within the throttle bore, thereby providing the operator with an indication of the amount of air being metered through valve 16.

[0012] A commutator magnet 46 is fixedly mounted on an end of rotor shaft 12 distal from motor 14. Commutator magnet 46 is typically cylindrical in shape and is positioned such that a gap is defined between commutator magnet 46 and lead frame interconnection assembly 18. Longitudinally defined quadrants of the cylindrical commutator magnet 46 comprise alternating

north and south poles configured such that magnetic flux lines radiate parallel to the axis of rotation of rotor shaft 12.

[0013] Also positioned on lead frame interconnection assembly 18 are commutation chips 48. Commutation chips 48 are magnets incorporated directly into lead frame interconnection assembly 18 at points adjacent the gap defined by commutator magnet 46 and lead frame interconnection assembly 18.

[0014] Another piece of electronic componentry disposed on lead frame interconnection assembly 18 is an insulator displacement terminal receptor 50. Insulator displacement terminal receptor 50 is configured to receive an insulator displacement terminal 51 disposed on the ends of motor leads 52 depending from a stator connector 54 of motor 14. Insulator displacement terminal receptor 50 is positioned on lead frame interconnection assembly 18 to provide electronic communication between the electronic componentry on lead frame interconnection assembly 18 and motor 14.

[0015] External electrical connector 22 is disposed on lead frame interconnection assembly 18 to provide a port into which an electrical lead (not shown) can be received and frictionally retained. External electrical connector 22 is in electronic communication with position sensor 44, insulator displacement terminal receptor 50, and commutator chips 48 through lead frame interconnection assembly 18. Lead frame interconnection assembly 18 has position sensor 44, insulator displacement terminal receptor 50, and commutator chips 48 integrally formed therein, thereby eliminating the need for separate mechanical interconnects and hand connections to be made.

[0016] Referring now to FIGURE 2, an embodiment in which the control valve assembly is modified to provide for linear actuation of a device is shown generally at 110 and is hereinafter referred to as "assembly 110". The device (not shown) requiring linear actuation may be a valve. Assembly 110 is substantially similar in structure and componentry to assembly 10 as shown in FIGURE 1. Assembly 110 comprises an output shaft 120 in operable communication with a motor 114 through a gear system. A lever 116 is disposed on and is in mechanical communication with output shaft 120. The gear system is substantially similar to the gear system of the embodiment of FIGURE 1. Motor 114 is in electronic communication with electronic componentry mounted on a lead frame interconnection assembly 18 positioned adjacent to the end of a rotor shaft 112 of motor 114 and an end of output shaft 120.

[0017] The gear system includes an output gear 130 disposed on output shaft 120. As rotor shaft 112 is axially rotated, torque is transferred through the gear system to output gear 130. As output gear 130 is rotated, lever 116 disposed on output shaft 120 is correspondingly moved to effectuate the linear translation of the componentry of the linearly actuatable device.

[0018] Referring now to FIGURE 3, motor 14, which

is incorporable in either assembly 10 of FIGURE 1 or assembly 110 of FIGURE 2, is shown in greater detail. Motor 14 includes motor leads 52, which are characterized by conductive elements 56 disposed within insulator displacement terminal 51. Conductive elements 56 provide for electrical communication between the stator of motor 14 and the insulator displacement terminal positioned on the lead frame interconnection assembly. [0019] While preferred embodiments have been shown and described, various modifications and substitutions may be made thereto without departing from the spirit and scope of the invention. Accordingly, it is to be understood that the present invention has been described by way of illustration only, and such illustrations and embodiments as have been disclosed herein are not to be construed as limiting to the claims.

Claims

1. A control valve assembly, comprising:

a contactless motor;
a control valve in mechanical communication with said contactless motor through a gear system; and
a lead frame interconnection assembly, said lead frame interconnection assembly having electronic componentry relevant to said contactless motor and said control valve integrally formed therein.

2. The control valve assembly of claim 1 wherein said contactless motor comprises a commutator magnet disposed on a rotor shaft thereof, said commutator magnet being in magnetic communication with at least two commutator chips integrally formed with said lead frame interconnection assembly.

3. The control valve assembly of claim 1 wherein said control valve comprises,
a throttle element disposed in a throttle bore,
an output shaft depending from said throttle element, and
at least one position sensing magnet disposed on an end of said output shaft distal from said throttle element.

4. The control valve assembly of claim 3 wherein said at least one position sensing magnet is in magnetic communication with at least one position sensor integrally formed with said lead frame interconnection assembly.

5. The control valve assembly of claim 4 wherein said at least one position sensing magnet is in magnetic communication with a position sense flux carrier integrally formed with said lead frame interconnection

assembly.

6. The control valve assembly of claim 1 wherein said lead frame interconnection assembly comprises an insulator displacement terminal receptor integrally formed therein, said insulator displacement terminal receptor being configured and dimensioned to receive an insulator displacement terminal from a stator of said contactless motor.
5
7. The control valve assembly of claim 1 wherein said lead frame interconnection assembly comprises an external electrical connector integrally formed therein, said external electrical connector being configured and dimensioned to provide electronic communication between an operator and said lead frame interconnection assembly.
10
8. The control valve assembly of claim 3 wherein said throttle element is a throttle plate rotatably positioned in said throttle bore.
20
9. The control valve assembly of claim 3 wherein said throttle element is a linearly translatable device.
25
10. A lead frame interconnection assembly, comprising:
a plurality of electronic componentry integrally formed therein.
30
11. The lead frame interconnection assembly of claim 10 wherein said electronic componentry comprises commutation chip magnets configured to be responsive to a commutator magnet disposed on a rotor shaft of a motor.
35
12. The lead frame interconnection assembly of claim 10 wherein said electronic componentry comprises at least one magnetic sensor configured to be responsive to at least one position sensing magnet disposed on an actuatable device.
40
13. The lead frame interconnection assembly of claim 12 wherein said actuatable device is a rotatably actuatable control valve.
45
14. The lead frame interconnection assembly of claim 12 wherein said actuatable device is a linearly actuatable control valve.
50
15. The lead frame interconnection assembly of claim 10 wherein said electronic componentry comprises an insulator displacement terminal receptor, said insulator displacement terminal receptor being configured to receive an insulator displacement terminal depending from a stator of a motor.
